Throw *n* balls randomly into *n* bins.

Throw *n* balls randomly into *n* bins.

Exercise: Max number in a bin is $\sim \log n / \log \log n$ (a.a.s.)

Throw *n* balls randomly into *n* bins.

Exercise: Max number in a bin is $\sim \log n / \log \log n$ (a.a.s.)

Theorem [Azar, Broder, Karlin and Upfal, '94]

Throw the balls sequentially, each ball put into the least-full of $h \ge 2$ randomly chosen bins. Then finally, max is $O(\ln \ln n / \ln h)$.

◆□▶ ◆□▶ ◆□▶ ◆□▶ ● ● ● ●

An application

Balance the load of machines, on-line. 'load' equals number of jobs assigned. *h* choices for each job. Then the max 'load' is about $(\ln \ln n) / \ln h$.

Conjecture

A.a.s. if $\overline{d} < hk - \epsilon$, where \overline{d} is the average degree in the (k+1)-core of $G \in \mathcal{G}(n, m, h)$, then G is k-orientable.

Theorem [Gao and W, '09]

The conjecture is true for fixed *k* provided it is sufficiently large.

(日) (日) (日) (日) (日) (日) (日)

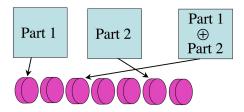

The threshold at which this occurs (core of h-uniform hypergraph gets average degree hk) is known. (Cain and Wormald; Molloy, Cooper, Janson and Luczak.)

Problem version 3. Even more to choose from

Storing two copies of every file requires double the space. More efficient storage strategy:

... and what if two disks fail? More general error correcting strategies.

Each file will need to choose w out of h disks, for some $1 \le w < h$.

More general orientations

A hyperedge is *w*-oriented if exactly *w* distinct vertices in it are marked with positive signs with respect to the hyperedge.

The indegree of a vertex is the number of positive signs it receives.

A (w, k)-orientation of an *h*-hypergraph is a *w*-orientation all hyperedges such that each vertex has indegree at most *k*. If such a (w, k)-orientation exists, we say the hypergraph is (w, k)-orientable.

Conjecture

The event

$$\sum_{j=0}^{w-1} (w-j)m_{h-j} < k\bar{n},$$

where

 m_{h-j} is the number of edges of cardinality h-j in the (w, k+1)-core of $G \in \mathcal{G}(n, m, h)$,

◆□▶ ◆□▶ ◆□▶ ◆□▶ ● ● ● ●

n is its number of vertices,

has the same sharp threshold as G being (w, k)-orientable.

Conjecture

The event

$$\sum_{j=0}^{w-1} (w-j)m_{h-j} < k\bar{n},$$

where

 m_{h-j} is the number of edges of cardinality h-j in the (w, k+1)-core of $G \in \mathcal{G}(n, m, h)$,

 \bar{n} is its number of vertices,

has the same sharp threshold as G being (w, k)-orientable. In particular (w, k)-orientability has a sharp threshold.

Theorem [Gao and W, '09]

The conjecture is true for fixed *k* sufficiently large.

We determine the threshold in terms of the solution of a system of differential equations.

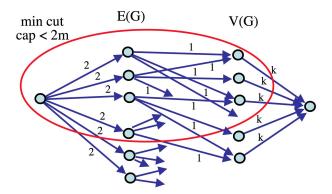

Proof approach

Look again at the flow formulation. E.g.: h = 3, w = 2.

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ ─臣 ─のへで

Proof approach

Look again at the flow formulation. E.g.: h = 3, w = 2.

From the flow:

Lemma

An *h*-hypergraph *G* can be (w, k)-oriented iff there is no set $S \subseteq V(G)$ with

$$\frac{1}{|\mathcal{S}|}\sum_{x\in E(G)} (|x\cap\mathcal{S}|-(h-w))^+ > k.$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ = 三 のへで

From the flow:

Lemma

An *h*-hypergraph *G* can be (w, k)-oriented iff there is no set $S \subseteq V(G)$ with

$$\frac{1}{|S|}\sum_{x\in E(G)} (|x\cap S|-(h-w))^+ > k.$$

Major result:

Sub-theorem

Let C denote the (w, k + 1)-core of $G \in \mathcal{G}(n, m, h)$. A.a.s. if

$$\frac{1}{|S|} \sum_{x \in E(G)} (|x \cap S| - (h - w))^+ < k - \epsilon$$

for S = C then it holds for all $S \subseteq V(G)$.

For S = C, the requirement becomes

$$\frac{1}{|\mathcal{C}|} \sum_{j=0}^{w-1} (w-j)m_{h-j} < k-\epsilon$$

where m_{h-j} is the number of edges of the core of size h-j. This gives the theorem.

If w = 1 this says the average degree is less than $h(k - \epsilon)$.

For S = C, the requirement becomes

$$\frac{1}{|\mathcal{C}|}\sum_{j=0}^{w-1}(w-j)m_{h-j} < k-\epsilon$$

where m_{h-j} is the number of edges of the core of size h-j. This gives the theorem.

If w = 1 this says the average degree is less than $h(k - \epsilon)$.

To prove the sub-theorem we need properties of the random (w, k + 1)-core.

For S = C, the requirement becomes

$$\frac{1}{|\mathcal{C}|}\sum_{j=0}^{w-1}(w-j)m_{h-j} < k-\epsilon$$

where m_{h-j} is the number of edges of the core of size h-j. This gives the theorem.

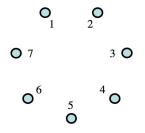

If w = 1 this says the average degree is less than $h(k - \epsilon)$.

To prove the sub-theorem we need properties of the random (w, k + 1)-core.

To study the threshold we also need properties of the random (w, k + 1)-core.

The differential equation method shows sharp concentration for the final core (solve numerically).

Even without d.e.'s we can prove (after considerable work, and for large k)

Sub-theorem

Let C denote the (w, k + 1)-core of $G \in \mathcal{G}(n, m, h)$. A.a.s. if

$$\frac{1}{|S|} \sum_{x \in E(G)} (|x \cap S| - (h - w))^+ < k - \epsilon$$

(日) (日) (日) (日) (日) (日) (日)

for S = C then it holds for all $S \subseteq V(G)$.

For large k we have shown that k-orienting the random h-uniform hypergraph has a threshold determined by the density of the (k + 1)-core. This generalises (for large k) the result known for graphs that proved Karp and Saks' conjecture, with a new simpler proof.

- For large k we have shown that k-orienting the random h-uniform hypergraph has a threshold determined by the density of the (k + 1)-core. This generalises (for large k) the result known for graphs that proved Karp and Saks' conjecture, with a new simpler proof.
- Even further generalising, existence of a (w, k)-orientation (k large) of the random h-uniform hypergraph is essentially determined by the existence of a subgraph with a certain 'density'.

- Even further generalising, existence of a (w, k)-orientation (k large) of the random h-uniform hypergraph is essentially determined by the existence of a subgraph with a certain 'density'.

• Conjecture the same results for all $k \ge 1$.

- Even further generalising, existence of a (w, k)-orientation (k large) of the random h-uniform hypergraph is essentially determined by the existence of a subgraph with a certain 'density'.
- Conjecture the same results for all $k \ge 1$.
- No fast algorithm for loadbalancing yet. Conjecture that the obvious generalisation of the load-degree algorithm does the job for all (w, k).
