The Renormalized Random Phase Approximation with Kernel Correction for Materials Science

Adrienn Ruzsinszky
Department of Physics
Temple University
Philadelphia

IPAM Summer School: Putting the Theory Back in Density Functional Theory
August 22 - 26, 2016
Motivation

To understand long-standing and fundamental problems in solid-state physics and materials chemistry with the random phase approximation (RPA)

• structural phase transitions are extremely difficult (and extremely difficult to realize experimentally)
• interlayer binding (sometimes double minima is found)
• adsorption (binding and site preference)
• weak interactions in molecules, biomolecules
• reaction energies of certain kinds (self-interaction exposed)
RPA in the density functional context

- Adiabatic connection: density is constrained to physical ($\lambda=1$) value. $\Phi_0$ is a single-determinant of Kohn-Sham orbitals

\[
E[n] = \left\langle \Phi_0[n] \right| \hat{H}_{\lambda=1} \left| \Phi_0[n] \right\rangle + E_c[n]
\]

\[
\hat{H}_\lambda[n] = \hat{T} + \hat{V}_{en} + \hat{V}_{nn} + \lambda \hat{V}_{ee}
\]

- Zero-temperature fluctuation-dissipation theorem:

\[
E_c = -\int_0^1 d\lambda \text{Re} \int_0^\infty \frac{du}{2\pi} \left\langle \nu(\vec{r} - \vec{r}') \left[ \chi_\lambda(iu) - \chi_0(iu) \right] \right\rangle
\]

$\chi_\lambda$: Density-density response function,
$\nu(\vec{r} - \vec{r}')$: bare Coulomb interaction

The total energy is computed as $E = \text{EXX} + \text{Ec}$, where EXX is the Hartree-Fock exact-exchange energy evaluated using KS orbitals.

Ren et al., J. Mater. Sci. 47, 7447 (2012)
Density-density Response Function

\[ \chi_{\lambda}^{-1}(\omega) = \chi_0^{-1}(\omega) - [v_{\lambda} + f_{xc}^{\lambda}(\omega)] \]

\[ \chi_{\lambda} = \chi_0 + \chi_0[v_{\lambda} + f_{xc}^{\lambda}]\chi_{\lambda} \]

- Poles of \( \chi_{\lambda} \) at excitations of interacting system
- Exact \( f_{xc}^{\lambda} \): spatially nonlocal complicated \( \omega \) behavior
- Approximate \( f_{xc} \) obtained from semilocal functionals or a model

\textbf{RPA:} \[ f_{xc}(\vec{r}_1, \vec{r}_2, \omega) = 0 \]

Applications of RPA

- Atomization energies were too low by typically 10 kcal/mol, in comparison to experiment.

- vdW interactions
  
  S22 data set, adsorption of organic molecules, i.e., benzene on metal surfaces, CO adsorption problem, graphene on metal surfaces

Although RPA is known for capturing vdW interactions, binding and cohesive energies are underestimated.

How does the overall underestimation of binding by RPA affect structural properties and structural phase transitions?
Local field corrections

An intrinsic way to remedy the drawbacks of RPA is to restore the kernel within the ACFDT framework.

How to approach the kernel?

• derive the kernel from microscopic theory
• satisfy exact, known constraints

Most models use the paradigm of the uniform electron gas

ALDA kernel

• The ALDA is the next-simplest approximation for the kernel:

\[ f^{\text{ALDA}}_{\text{xc}} [n](\vec{r}, \vec{r}') = \delta(\vec{r} - \vec{r}') \frac{d^2[n\varepsilon^{\text{unif}}_{\text{xc}} (n)]}{dn^2} \bigg|_{n=n(\vec{r})} \]

\( \varepsilon^{\text{unif}}_{\text{xc}} (n) \) is the exchange-correlation energy per particle of an electron gas of uniform density

• ALDA is not exact for the homogeneous electron gas
• ALDA gives reasonable accuracy for low-frequency, long-wavelength excitations, but is not the right choice for a correction to RPA.
• Lein, Gross and Perdew studied the correlation energy per particle of the uniform gas using various kernels. They found that RPA and ALDA-corrected RPA make errors of about 0.5 eV, of opposite sign.
• ALDA is divergent in its correlation hole

What is known about the exchange-correlation kernel?

(1) Why does the ALDA kernel fail even for the uniform electron gas?
• is not exact even for the static exchange-correlation kernel of the uniform electron gas.
• arbitrary small density variations around the uniform density requires a two-point density functional or double integral over the three-dimensional space, while LDA is only a one-point density functional or single integral.

(2) Can a static kernel give accurate exchange-correlation energies?
• Ghosez, Gonze, and Godby had shown that the static kernel in an insulator at the exchange-only level has “ultranonlocality”, decaying at large like a negative constant over \( u \).

(3) Can we neglect the correlation part of the kernel?
• it is exact by construction in the high-density limit

(4) Error cancellation between exchange and correlation
• the NEO kernel is ultranonlocal for insulators and molecules as well

Introducing the NEO (nonlocal energy-optimized) kernel

Three state-of-the-art features:

- self-interaction correction
- energy-optimization
- ultranonlocality
NEO kernel: Short-range correction to the RPA correlation energy, for solid metals

Based on the knowledge of the uniform electron gas.

The exact $xc$ kernel in the uniform electron gas is known to be nonlocal but short-ranged, and our initial version of a NEO kernel also has these features:

$$f_{xc}^{\lambda,NEO} ([n_{\uparrow}, n_{\downarrow}], \vec{R}, u) = -\frac{\lambda}{u} \sum_\sigma \left( \frac{n_\sigma}{n} \right)^2 e^{-c(1-z_\sigma^2)k_{F\sigma}^2u^2}$$

$$n = n_{\uparrow} + n_{\downarrow},$$

$$k_{F\sigma} = (6\pi^2n_\sigma)^{1/3}, \quad z_\sigma = tau_{\sigma}^{VW} / tau, \quad tau_{\sigma}^{VW} = |\nabla n_\sigma|^2 / 8n_\sigma$$

$$tau_\sigma = 1/2 \sum_\alpha occ \left| \nabla \phi_{\alpha\sigma} \right|^2 .$$

The one-electron limit:

The singlet two-electron limit:

The uniform electron gas limit is:

The short-range limit:

The long-range limit:

$$f_{xc}^{\lambda,NEO} = -\lambda / u$$

$$f_{xc}^{\lambda,NEO} = -\lambda / 2u$$

$$(-\lambda / u) \sum (n_\sigma / n)^2 e^{-c k_{F\sigma}^2 u^2}$$

$$(-\lambda / u) \sum_\sigma (n_\sigma / n)^2$$

$$f_{xc}^{\lambda,NEO} \sigma \to 0$$
Fitting to the second-order correlation energy

Correlation energy of the uniform electron gas:

\[ e^{RPA}_c = -\frac{12}{\pi} \frac{\hbar^2}{m\alpha_0^2 r_s^2 a_0^2} \int_0^\infty dQ \int_0^\infty dWQ^2 \left[ \alpha(Q,W) - \ln \{1 + \alpha(Q,W)\} \right] \]

\[ Q = \frac{k}{2k_F}, \quad W = \frac{\Omega}{2k_F^2} \]

\[ \alpha(Q,W) \] is first-order in \( r_s \).

\[ f(\alpha) = \alpha - \frac{1}{2} \alpha^2 + ... \]

Second-order exchange energy with the local-field factor:

\[ e^{2X}_c = \frac{3}{8\pi^3} \int_0^\infty dQ \tilde{G}_x(Q) \int_0^\infty dWQ^2 \{2\beta\}^2 \]

The “c” parameter in NEO provides a unique fit to the exact second-order correlation energy for the spin-unpolarized electron gas. It can be evaluated from explicit expressions given by von Barth and Hedin for RPA and by Langreth and Perdew beyond RPA. It is designed to yield the exact second-order exchange energy of the uniform gas, which is itself an average over frequencies.

# Atomization energies

Deviation from reference CCSDTQ atomization energies for 19 small molecules from the HEAT set for the NEO kernel, direct RPA and SOSEX (kcal/mol).

RPA Renormalization

\[ \chi_\lambda = [1 - \chi_0 (v_\lambda + f_{xc}^\lambda)]^{-1} \chi_0 \]

\[ \chi_\lambda = \hat{\chi}_\lambda + \hat{\chi}_\lambda f_{xc}^\lambda \chi_\lambda \]

\( \hat{\chi}_\lambda \): RPA response function

first order approximation =

RPAr1 with the NEO kernel

Replacing \( \hat{\chi}_\lambda \) by \( \chi_0 \)

\[ \chi_\lambda = \hat{\chi}_\lambda + \chi_0 f_{xc}^\lambda \hat{\chi}_\lambda \]

ACSOSEX with the NEO kernel

Both RPAr1 and ACSOSEX yield the exact second-order, unscreened perturbative correlation energy when the exact first-order kernel is used, but differ in their higher-order contributions.

ACSOSEX vs. RPAr1: homogeneous electron gas

The error from PW92 as a function of $r_s = 4$ for $c = 0.264$.

- ACSOSEX overestimates, RPAr1 underestimates $\Delta E_{\text{C}}^{b\text{RPA}}$
- RPAr1 systematically recovers $> 90\%$ of $\infty$-order $\Delta E_{\text{C}}$
- Structural properties show identical trends
ACSOSEX vs. RPAr1: inhomogeneous systems

RPAr1: NEO in RPAr1
HOT: NEO in RPAr1
ACSOSEX: NEO in RPAr1-ACSOSEX

Higher order terms (HOT)

Finite-order RPAr:

\[
\chi_\lambda = \hat{\chi}_\lambda + \hat{\chi}_\lambda f_{xc}^\lambda \hat{\chi}_\lambda + \hat{\chi}_\lambda f_{xc}^\lambda \hat{\chi}_\lambda f_{xc}^\lambda \hat{\chi}_\lambda + \ldots
\]

The n-th order RPAr correction: The n-th order RPAr correction is:

\[
E_c = E_c^{RPA} + \sum_{n=1}^{\infty} \Delta E_c^{RPA-n}[f_{xc}] \quad \Delta E_c^{RPA-n}[f_{xc}] = -\int_0^1 d\lambda \int_0^{2\pi} \left( v(\hat{\chi}_\lambda(iu)f_{xc}^\lambda(iu))^n \hat{\chi}_\lambda(iu) \right)
\]

For the n-th order correction analytical integration wrt. \( \lambda \) is not feasible.

Solution: an approximation based on the AC formula

\[
\Delta E_c^{bRPA}[f_{xc}] = \sum_{n=2}^{\infty} \Delta E_c^{RPA-n} \approx (1 - \hat{b}) \Delta U_c^{RPA2} \approx \frac{1}{2} \Delta U_c^{RPA2}
\]

\( \Delta U_c^{RPA2} \) can be estimated from the coupling-strength integral at \( \lambda = 1 \)

\[
E_c^{HOT}[f_{xc}] = E_c^{RPA} + \Delta E_c^{RPA1}[f_{xc}] + \frac{1}{2} \Delta U_c^{RPA2}[f_{xc}]
\]
RPA renormalization contributions to the RPA correlation energy with NEO, rALDA and CP07 kernels for the uniform electron gas at $r_s = 4$. The HOT correction is plotted for comparison with RPAr2-4.
Another paradigm in condensed matter physics: Jellium surface

Metal surface energies can be treated within the jellium model: valence electrons are neutralized by a positive background.

The ACFDT formalism was used for the jellium surface energy by Pitarke and Eguiluz.

In 2000, Yan, Perdew and Kurth argued that the correction to RPA, although large (about +0.5 eV per electron), would tend to cancel almost completely out of energy differences for processes that conserve electron number.

RPA can be expected to much better for the surface energy than for the bulk energy of a solid.
Jellium slab with finite width

The surface energy of jellium is the work invested to create a unit area of new surface:

$$\sigma_{xc} = \int_{-\infty}^{\infty} dz n(z) \left\{ \varepsilon_{xc} ([n, z]) - \varepsilon_{xc}^\text{unif} (\bar{n}) \theta(z_0 - z) \right\}$$

bulk contributions cancel

The xc energy contributions to the bulk and surface can be interpreted by the wavevector decomposition:

Jellium slab: $$\varepsilon_{xc} = \int_{0}^{\infty} d\left( \frac{q_\parallel}{2k_F} \right) \varepsilon_{qc}^{\parallel}$$

Jellium surface: $$\sigma_{xc} = \int_{0}^{\infty} d\left( \frac{q_\parallel}{2k_F} \right) \gamma_{q_\parallel}^{xc}$$

The $$q_\parallel$$ wavevector analysis:

$$\gamma_{q_\parallel}^{xc} = \frac{k_f}{8\pi} \int dz \int dz' n(z) v_{q_\parallel} \left( |z - z'| \right) \int_{0}^{1} d\lambda \left[ n_{q_\parallel,\lambda}^{xc} (z, z') - \bar{n}_{q_\parallel,\lambda}^{xc} (|z - z'|) \right]$$

$$q_\parallel$$ : wave vector parallel to surface

$$z$$ : direction perpendicular to surface
Jellium surface energy within RPA

Invoke the xc hole integral:

\[
E_{xc} = \frac{1}{2} \int dr \int dr' \frac{n(\vec{r})n_{xc}(\vec{r}, \vec{r}')}{|\vec{r} - \vec{r}'|}
\]

The xc hole density comes from the fluctuation dissipation theorem:

\[
n_{xc}(\vec{r}, \vec{r}') = \int_0^1 d\lambda n_{xc,\lambda}(\vec{r}, \vec{r}')
\]

The density response function comes from the Dyson equation with or without the kernel:

\[
\chi_{q,\lambda}(z, z', \omega) = \chi_{q,\lambda}^0(z, z', \omega) + \int dz_1 \int dz_2 \chi_{q,\lambda}^0(z, z_1, \omega) \times \\
\left[ \chi_{q,\lambda}(z_1 - z_2) + f_{q,\lambda}(z_1, z_2, \omega) \right] \chi_{q,\lambda}(z_2, z', \omega)
\]
NEO kernel for jellium surface

NEO-I

\[ f_{xc}^{\alpha,\text{NEO}}(n \uparrow, n \downarrow, \vec{R}, u) = -\frac{\lambda}{u} \sum_{\sigma} \left( \frac{n_\sigma}{n} \right)^2 \text{erfc}(au) \quad a = \sqrt{\tilde{c} \left( 1 - Z_{\sigma}^2 \right) k_{F, \sigma}^2} \]

Problem for jellium: it produces a long-ranged exchange kernel in the tail of the density of a jellium surface, since \( Z \to 1 \) and \( k_F \to 0 \) there.
The relevance of the meta-GGA ingredients

\[ z = \tau / \tau^{\text{VW}} \quad \alpha = (\tau - \tau^{\text{VW}}) / \tau^{\text{unif}} \quad t^{-1} = \tau / \tau^{\text{unif}} \]

1) Regions of one- and two-electron density:

\[ \tau = \tau^{\text{VW}} \quad z = 1 \quad t^{-1} = 5s^2 / 3 \quad \alpha = 0 \quad \text{(single bonds)} \]

2) Regions of uniform density:

\[ \tau^{\text{VW}} = 0 \quad z = 0 \quad t^{-1} = 1 \quad \alpha = 1 \quad \text{(metallic bonds)} \]

3) Regions of density overlap between closed shells:

\[ \tau^{\text{VW}} \approx 0 \quad z \approx 0 \quad t^{-1} \rightarrow \infty \quad \alpha \rightarrow \infty \quad \text{(weak bonds)} \]

\[ \tau / \tau^{\text{unif}} \sim n / n^{5/3} \quad \text{as} \quad n \rightarrow 0 \quad t^{-1} \rightarrow \infty \]

Only \( \alpha \) can recognize these three regions and treat them differently.

Solution: make use of our knowledge of recent meta-GGA’s

Replace \( (1 - Z^2_\sigma) \) by \( 3\alpha_\sigma - 3\alpha^2_\sigma + \alpha^3_\sigma \). This leads to: NEO-II

\[
f_{xc}^{\alpha,\text{NEO}}(n \uparrow, n \downarrow, \bar{R}, u) = -\frac{\lambda}{u} \sum_\sigma \left( \frac{n_\sigma}{n} \right)^2 \text{erfc}(au)
\]

\[
a = \sqrt{\tilde{c} \left( \alpha_\sigma - 3\alpha^2_\sigma + 3\alpha^3_\sigma \right) k^2_{F,\sigma}}
\]

\[
\alpha = (\tau - \tau^\text{VW}) / \tau^\text{unif}
\]

properly diverges in the tail

We do not refit parameter “c” when switch from NEO-I to NEO-II

NEO-II leaves unchanged the correct NEO behaviors for one- and two-electron densities ($\alpha = 0$) and slowly-varying densities ($\alpha = 1 + O(\nabla^2)$), but kills of the kernel in the tail of the surface density ($\alpha \to \infty$)

Comparison between $k_{2F}(1-Z^2)$ and $k_{2F}(\alpha-3\alpha^2+\alpha^3)$ at a jellium surface of bulk parameter $r_s = 6$. The surface is at $z = 0$, the bulk is at $z < 0$, and the vacuum is at $z \to \infty$
Two-dimensional wavevector analysis of the correlation energy per particle of the jellium slab with width $= 2.23\lambda_F$ ($\lambda_F = 2\pi/k_F$), and $rs = 2.07$ for ISTLS, RPA, and the NEO kernels.

$rs = 2.07$ corresponds to Al(100) surface

Two-dimensional wavevector analysis of the jellium surface energy with $rs = 2.07$ for ISTLS, RPA, and the NEO kernels. Surface energy is the area below the curves.
Jellium correlation surface energies with different approaches at background parameter $r_s = 2.07$

Exchange-correlation and correlation energies along the “z” direction in the jellium slab
Conclusions

• RPA energies require a substantial kernel correction.

• The standard ALDA kernel used in TDDFT is as bad as no kernel at all.

• The kernel can be modelled by satisfaction of exact constraints, e.g.; the NEO kernel.

• The kernel can be included exactly to all orders, but RPA renormalization is less expensive and almost as accurate.

• The kernel has a major effect on the correlation energy of bulk jellium, but much less effect on the jellium surface energy.
