# Lambertian model of reflectance I: shape from shading and photometric stereo 

## Ronen Basri

Weizmann Institute of Science

## Variations due to lighting (and pose)

Dumitru Verdianu
Flying Pregnant Woman

## Edges

## Edges on smooth surfaces

## Bump or dip?

## What sticks out?

## Light field

- Rays travel from sources to objects
- There they are either absorbed or reflected
- Energy of light decreases with distance and number of bounces
- Camera is designed to capture the set of rays that travel through the focal center
- We will assume the camera response is linear

## Specular reflectance (mirror)

- When a surface is smooth light reflects in the opposite direction of the surface normal

## Specular reflectance

- When a surface is slightly rough the reflected light will fall off around the specular direction

## Diffuse reflectance

- When the surface is very rough light may be reflected equally in all directions

## Diffuse reflectance

- When the surface is very rough light may be reflected equally in all directions

## BRDF

- Bidirectional Reflectance Distribution Function

$$
f\left(\theta_{\text {in }}, \emptyset_{\text {in }} ; \theta_{\text {out }}, \emptyset_{\text {out }}\right)
$$

- Specifies for a unit of incoming light in a direction $\left(\theta_{\text {in }}, \emptyset_{\text {in }}\right)$ how much light will be reflected in a direction $\left(\theta_{\text {out }}, \emptyset_{\text {out }}\right)$

## BRDF

Light from front Light from back

## Lambertian reflectance

## Lambertian reflectance

## Lambert's law

$$
\begin{aligned}
& I=E \rho \cos \theta\left(\theta \leq 90^{\circ}\right) \\
& I=\vec{l} \vec{n} \vec{l}(\vec{l}=E \hat{l}, \vec{n}=\rho \hat{n})
\end{aligned}
$$

## Preliminaries

- A surface is denoted $z(x, y)$
- A point on $z$ is $(x, y, z(x, y))$
- The tangent plane is spanned by

$$
\left(1,0, z_{x}\right) \quad\left(0,1, z_{y}\right)
$$

- The surface normal is given by

$$
\hat{n}=\frac{1}{\sqrt{z_{x}^{2}+z_{y}^{2}+1}}\left(-z_{x},-z_{y}, 1\right)
$$

## Photometric stereo

- Given several images of the a lambertian object under varying lighting
- Assuming single directional source

$$
M=L S
$$

## Photometric stereo

$$
\begin{gathered}
M=L S \\
{\left[\begin{array}{ccc}
I_{11} & \cdots & I_{1 p} \\
\vdots & & \vdots \\
\vdots & & \vdots \\
I_{f 1} & \cdots & I_{f p}
\end{array}\right]_{f \times p}=\left[\begin{array}{ccc}
l_{1 x} & l_{1 y} & l_{1 z} \\
& \vdots & \\
l_{f x} & l_{f y} & l_{f z}
\end{array}\right]_{f \times 3}\left[\begin{array}{llll}
n_{x 1} & & & n_{x p} \\
n_{y 1} & \cdots & \cdots & n_{x p} \\
n_{z 1} & & & n_{x p}
\end{array}\right]_{3 \times p}}
\end{gathered}
$$

- We can solve for $S$ if $L$ is known (Woodham)
- This algorithm can be extended to more complex reflection models (if known) through the use of a lookup table

## Factorization (Hayakawa)

- Use SVD to find a rank 3 approximation

$$
M=U \Sigma V^{T}
$$

- Define $\Sigma_{3}=\operatorname{diag}\left(\sigma_{1}, \sigma_{2}, \sigma_{3}\right)$, where $\sigma_{1}, \sigma_{2}, \sigma_{3}$ are the largest singular values of $M$

$$
\hat{L}=U \sqrt{\Sigma_{3}}, \quad \hat{S}=\sqrt{\Sigma_{3}} V^{T} \text { and } M \approx \hat{L} \hat{S}
$$

- Factorization is not unique, since
$\widehat{M}=\left(\hat{L} A^{-1}\right)(A \hat{S}), A$ is $3 \times 3$ invertible
- We can reduce ambiguity by imposing integrability

## Generlized bas-relief ambiguity

 (Belhumeur, Kriegman and Yuille)- Linearly related surfaces: given a surface $z(x, y)$ the surfaces related linearly to $z$ are:

$$
\begin{gathered}
\tilde{z}(x, y)=a x+b y+c z(x, y) \\
G=\left[\begin{array}{lll}
1 & 0 & 0 \\
0 & 1 & 0 \\
a & b & c
\end{array}\right] \quad G^{-1}=\frac{1}{c}\left[\begin{array}{ccc}
c & 0 & 0 \\
0 & c & 0 \\
-a & -b & 1
\end{array}\right]
\end{gathered}
$$

- Forms a sub-group of GL(3)

## Bas-relief

## Integrability

- Objective: given a normal field $n(x, y) \in S^{2}$ recover depth $z(x, y) \in \mathbb{R}$
- Recall that

$$
n=\left(n_{x}, n_{y}, n_{z}\right)=\frac{\rho}{\sqrt{z_{x}^{2}+z_{y}^{2}+1}}\left(-z_{x},-z_{y}, 1\right)
$$

- Given $n$, we set

$$
\rho=\|n\| ; p=-\frac{n_{x}}{n_{z}}, q=-\frac{n_{y}}{n_{z}}
$$

## Integrability

- Solve
$\min _{z(x, y)}(z(x+1, y)-z(x, y)-p)^{2}+(z(x, y+1)-z(x, y)-q)^{2}$
where

$$
p=-\frac{n_{x}}{n_{z}}, q=-\frac{n_{y}}{n_{z}}
$$

Photometric stereo with matrix completion (Wu et al.)

## Shape from shading (SFS)

- What if we only have one image?
- Assuming that lighting is known and albedo is uniform

$$
I=\overrightarrow{l^{T}} \vec{n} \propto \cos \theta
$$

- Every intensity determines a circle of possible normals
- There is only one unknown ( $z$ ) for each pixel
(since uniform albedo is assumed)

## Shape from shading

- Denote $n=\left(-z_{x},-z_{y}, 1\right)$
- Then

$$
E=\frac{l^{T} n}{\|n\|}
$$

- Therefore

$$
E^{2} n^{T} n=n^{T} l l^{T} n
$$

- We obtain

$$
n^{T}\left(l l^{T}-E^{2} I\right) n=0
$$

- This is a first order, non-linear PDE (Horn)

## Shape from shading

- Suppose $l=(0,0,1)$, then

$$
z_{x}^{2}+z_{y}^{2}=\frac{1}{E^{2}}-1
$$

- This is called an Eikonal equation

## Distance transform

- The distance of each point to the boundary

## Shortest path

## Distance transform

- Posed as an Eikonal equation

$$
\|\nabla z\|^{2}=z_{x}^{2}+z_{y}^{2}=1
$$

## Update for shortest path

$$
\begin{gathered}
\begin{array}{l}
\text { Update for fast marching } \\
\text { (Tsitsiklis, Sethian) }
\end{array} \\
T=\left\{\begin{array}{cc}
T_{1}+T_{2}+\sqrt{2 f^{2}-\left(T_{1}-T_{2}\right)^{2}} & \text { if real } \\
f+\min \left\{T_{1}, T_{2}\right\} & \text { otherwise }
\end{array}\right.
\end{gathered}
$$

## SFS Solution (Kimmel \& Sethian)

- Lambertian SFS produces an eikonal equation

$$
\|\nabla z\|^{2}=z_{x}^{2}+z_{y}^{2}=\frac{1}{E^{2}}-1
$$

- Right hand side determines "speed"
- Boundary conditions are required: depth values at local maxima of intensity and possibly in shape boundaries
- The case $l \neq(0,0,1)$ is handled by change of variables

## Example

## Summary

- Understanding the effect of lighting on images is challenging, but can lead to better interpretation of images
- We considered Lambertian objects illuminated by single sources
- We surveyed two problems:
- Photometric stereo
- Shape from shading

## Challenges

- General reflectance properties
- Lambertian
- specular
- general BRDFs
- Generic lighting
- multiple light sources ("attached shadows")
- near light
- Cast shadows
- Inter-reflections
- Dynamic scenes
- Local approaches (eg. direction of gradients) Can we hope to model this complexity?
