Estimator

Network design

Local  
Estimation

Other Results

- The purpose of sensor networks is to *sense*; i.e., to enable detection, estimation, classification, and tracking
- To exploit network structure, data at the nodes must be *registered*
  - Intrinsic data; e.g., clocks, platform orientation
  - Extrinsic data: collected by sensors

# Introduction

Other Results

- *Vertex labels:* An element of a Lie group  $G$  is associated with each node of a graph modeling a network
- *Edge labels:* An element of  $G$  representing a noisy measurement of the difference of the values on the vertices at either end
- *Goal:* Make the best estimate of the *connection* – the true relative offsets between the vertex values

Data Model  
Maximum-likelihood  
Estimator  
Network design

Local  
Estimation

Other Results

- Denote by  $f(x|\theta)$  a family of probability density functions parameterized by elements  $\theta$  on a manifold  $M$
- For given data  $x$ ,  $f(x|\theta)$  defines the likelihood function on  $M$
- A maximum-likelihood (ML) estimate for  $\theta$  is defined by

$$\hat{\theta} = \arg \max_{\theta \in M} f(x|\theta)$$

- The log-likelihood function  $\ell(x|\theta) : M \rightarrow \mathbb{R}$  is defined by

$$\ell(x|\theta) = \log f(x|\theta)$$

- A natural measure of discrimination on  $M$  is the Kullback-Leibler divergence

$$D(f_\theta || f_{\theta'}) = \int f(x|\theta) \log \frac{f(x|\theta)}{f(x|\theta')} dx$$

noise on  $\mathbb{R}$

Data Model  
Maximum-likelihood  
Estimator  
Network design

Local  
Estimation

Other Results

- Although the KL divergence is not symmetric, locally it gives a metric on  $M$  called the Fisher information metric
  - $F = E[d\ell \otimes d\ell]$
  - $F$  can also be computed as  $F = -E[\nabla^2 \ell]$ , for any connection
- The corresponding volume form

$$\text{vol}_F = \sqrt{\det F} d\theta_1 \wedge \cdots \wedge d\theta_m$$

is the Jeffreys prior

Geometry

Gauge-invariant  
Estimation

Graphs

Gaussian  
noise on  $\mathbb{R}$

Data Model

Maximum-likelihood  
Estimator

Network design

Local  
Estimation

Other Results

- The state of the network is a  $G$ -valued function  $x$  on  $V(\Gamma)$  but it is never directly observed
  - If the network were aligned, the function would be constant (flat connection)
- What is observed is the connection  $\omega \in \Omega = G^m$ 
  - In the absence of noise, for an aligned network this is the identity connection
  - If the network is not aligned, a gauge transformation can be found that takes  $\omega$  to the identity

$$x_v \mapsto g_v x_v \qquad \omega_e \mapsto g_{t(e)} \omega_e g_{s(e)}^{-1}$$

Network design

Local  
Estimation

Other Results

- Directed graph  $\Gamma$  with vertex set  $V(\Gamma)$  and edge set  $E(\Gamma)$

$$|V(\Gamma)| = n \quad |E(\Gamma)| = m$$

- Vertex space  $C_0(\Gamma)$  – functions from  $V(\Gamma)$  to  $\mathbb{R}$ ; a real vector space:

$$\mathbf{f} = \sum_{j=1}^n f_j \mathbf{v}_j \quad \mathbf{v}_j(v_\ell) = \delta_{j\ell}$$

- Edge space  $C_1(\Gamma)$  – functions from  $E(\Gamma)$  to  $\mathbb{R}$

$$\boldsymbol{\omega} = \sum_{j=1}^m \omega_j \mathbf{e}_j \quad \boldsymbol{\omega}_j(\omega_\ell) = \delta_{j\ell}$$

Local  
Estimation

Other Results

- Cycle space  $Z(\Gamma)$ : A *cycle* is a closed path in  $\Gamma$ ; i.e., a sequence of vertices  $\mathcal{L} = v_1 v_2 \dots v_q$  where  $v_i$  is adjacent to  $v_{i+1}$  for  $i = 1, \dots, q$  and  $v_q$  is adjacent to  $v_1$

$$z_{\mathcal{L}}(e_j) = \begin{cases} 1 & \text{if } e_j \in \mathcal{L} \text{ and } e_j \text{ is oriented as } \mathcal{L} \\ -1 & \text{if } e_j \in \mathcal{L} \text{ and } e_j \text{ is oriented opposite to } \mathcal{L} \\ 0 & \text{otherwise} \end{cases}$$

- $Z(\Gamma)$  is the linear subspace of  $C_1(\Gamma)$  spanned by the  $z_{\mathcal{L}}$
- *Kirchoff's current law (KCL)*:  $Z(\Gamma) = \ker D$ ; i.e.,  $Dz = 0$  for all  $z \in Z(\Gamma)$

$$\sum_{t(e_j)=v} e_j - \sum_{s(e_j)=v} e_j = \mathbf{0} \quad \forall v \in V(\Gamma)$$

Data Model

Maximum-likelihood

Estimator

Network design

Local  
Estimation

Other Results

- Cocycle space  $B(\Gamma)$ : The orthogonal complement of  $Z(\Gamma)$  in  $C_1(\Gamma)$ 
  - For any  $z \in Z(\Gamma)$  and  $\omega \in B(\Gamma)$ ,  $\langle z, \omega \rangle_{C_1} = 0$
- $B(\Gamma)$  is the image of  $C_0(\Gamma)$  under the coboundary operator; i.e., every  $\omega \in B(\Gamma)$  can be written as  $\omega = D^T x$  for some  $x \in C_0(\Gamma)$
- This gives *Kirchhoff's voltage law (KVL)*

# Gaussian noise on $\mathbb{R}$

Gaussian  
noise on  $\mathbb{R}$

Data Model  
Maximum-likelihood  
Estimator  
Network design

Local  
Estimation

Other Results

- The data has the form  $\mathbf{r} \in C_1(\Gamma)$

$$\mathbf{r} = \boldsymbol{\omega} + \boldsymbol{\varepsilon}$$

- The true offsets satisfy  $\boldsymbol{\omega} \in B(\Gamma)$  (KVL)
- The noise  $\boldsymbol{\varepsilon} \in C_1(\Gamma)$  has probability density

$$f(\boldsymbol{\varepsilon}) = \frac{1}{\sqrt{(2\pi)^m \det R}} \exp\left(-\frac{1}{2} \langle \boldsymbol{\varepsilon}, \boldsymbol{\varepsilon} \rangle_R\right)$$

where

$$\langle \boldsymbol{\varepsilon}, \boldsymbol{\varepsilon} \rangle_R = \boldsymbol{\varepsilon}^\top R^{-1} \boldsymbol{\varepsilon}$$

Gaussian  
noise on  $\mathbb{R}$

Data Model  
Maximum-likelihood  
Estimator  
Network design

Local  
Estimation

Other Results

- The conditional density for  $r$  given  $\omega$  is

$$f(\varepsilon|\omega) = \frac{1}{\sqrt{(2\pi)^m \det R}} \exp\left(-\frac{1}{2} \langle \mathbf{r} - \omega, \mathbf{r} - \omega \rangle_R\right)$$

- The maximum-likelihood estimate of  $\omega$  is

$$\hat{\omega} = \arg \min_{\omega \in B(\Gamma)} \langle \mathbf{r} - \omega, \mathbf{r} - \omega \rangle_R$$

# Gaussian noise on $\mathbb{R}$

## ML Estimator

- The data may be written as  $r = \hat{\omega} + \hat{\varepsilon}$  with  $\hat{\omega} \in B(\Gamma)$  (KVL) and

$$\langle \hat{\omega}, \hat{\varepsilon} \rangle_R = 0$$

i.e., the “residual”  $\hat{\varepsilon}$  satisfies

$$R^{-1}(\hat{\varepsilon}) \in Z(\Gamma) \text{ (KCL)}$$

# Gaussian noise on $\mathbb{R}$

Estimator  
Network design

Local  
Estimation

Other Results

- Weighted graph Laplacian  $L : C_0(\Gamma) \rightarrow C_0(\Gamma)$

$$L = DR^{-1}D^T$$

- Not invertible since  $\ker L$  contains constant functions in  $C_0(\Gamma)$
- Choosing a reference vertex, the offset estimator  $\hat{x} \in W$  is

$$\hat{x} = L_W^{-1}R^{-1}\mathbf{r}$$

where  $L_W$  (and  $D_W$  below) are defined with respect to the reduced vertex set

- The connection estimate is  $\hat{\omega} = D_W^T \hat{x}$

$$\hat{\omega} = D_W^T L_W^{-1} D_W R^{-1} \mathbf{r}$$

$D_W^T L_W^{-1} D_W R^{-1}$  is the  $R$ -orthogonal projection into  $B(\Gamma)$

Data Model  
Maximum-likelihood  
Estimator  
Network design

Local  
Estimation

Other Results

- For  $R = \text{diag}(\sigma_1^2, \dots, \sigma_m^2)$ , the Fisher information determinant is

$$\det F = \sum_S \prod_{e_j \in S} \frac{1}{\sigma_j^2}$$

where the sum is over all spanning trees  $S$  in  $\Gamma$

- The estimator  $\hat{x}$  is unbiased and

$$\det C_{\hat{x}} = \left( \sum_S \prod_{e_j \in S} \frac{1}{\sigma_j^2} \right)^{-1}$$

Data Model  
Maximum-likelihood  
Estimator  
Network design

Local  
Estimation

Other Results

- For  $R = \text{diag}(\sigma_1^2, \dots, \sigma_m^2)$ , the ML estimator residual satisfies KCL; i.e.,

$$DR^{-1}(\mathbf{r} - \hat{\boldsymbol{\omega}}) = \mathbf{0}$$

- Thus  $\hat{\boldsymbol{\omega}} = D^T \mathbf{x}$  for some  $\mathbf{x} \in C_0(\Gamma)$  (KVL)
- So  $L\mathbf{x} = DR^{-1}\mathbf{r}$  where  $L = DR^{-1}D^T$  is the weighted graph Laplacian
- *Any solution to this equation will serve for the local estimation algorithm*

Data Model  
Maximum-likelihood  
Estimator  
Network design

Local  
Estimation

Other Results

- Jacobi's Method gives a locally implementable solution
- The Laplacian can be written as  $L = N - A$  where  $N$  is the degree map and  $A$  is the adjacency map for  $\Gamma$
- Jacobi's method entails the iteration

$$\mathbf{x}_{n+1} = N^{-1}(DR^{-1}\mathbf{r} + A\mathbf{x}_n)$$

i.e., “be the average of what your neighbors think you are”

- Jacobi's method is guaranteed to converge if  $L$  is diagonally dominant; i.e.,  $|L_{ii}| > \sum_{i \neq j} |L_{ij}|$
- Unfortunately  $|L_{ii}| = \sum_{i \neq j} |L_{ij}|$ , so convergence is not guaranteed

Other Results

- Extension to  $G = \mathbb{R}^d$  – solutions have a tensor structure
- Von Mises noise on  $\mathbb{T}$  – oscillator phase alignment
  - Includes localizable fast algorithms that converge to near-ML estimates in all cases tested
  - Algorithm: “Be the weighted circular mean of what your neighbors think you are” where the weights come from how well the neighbors are aligned with their neighbors
- Compact connected abelian Lie groups follow the form of  $\mathbb{R}$  and  $\mathbb{T}$ , but suitable noise models are a problem
- Making progress in the non-abelian Lie group setting, including the important special case  $G = SO(3)$
- New work focusing more on estimation of parameters from extrinsic data on a sensor network
