Multi-Reference Coupled Cluster Method

Reinhold Schneider (TU Berlin) & S. Kvaal ( & A. Laestadius (University of Oslo) & F. Faulstich )

IPAM; 2023
Overview:

I. Motivation

IIa. Coupled Cluster Method (TCCSD)

IIa. Complete Active Space Coupled Cluster Method (CAS-SS)

III. Bivariational Formulation

IV. Theoretical Results and Conclusions
Motivation

Given the electronic Schrödinger equation

$$H \Psi = E \Psi$$

the wave function $\Psi$ can be approximated

- by a possible nonlinear parametrization, e.g. as tensor network (matrix product) states $\Psi \in \mathcal{M} \Rightarrow$ DMRG
- or nonlinear parametrization, e.g. single reference coupled cluster CC $\Psi = e^T \Phi_0$, $\Phi_0$ reference Slater determinant.
- multi-reference CC ansatz

$$\Psi \in \text{span}\{e^T_j \Phi_j : \Phi_j \in \mathcal{H}_{\text{cas}}, j = 0, \ldots, n-1\}$$

where $\mathcal{H}_{\text{cas}}$ is a possibly not too large subspace generated by Slater determinants (Full CI Space)

- here we are interested in the first $n$ Eigenfunctions for $E_0, \ldots, E_{n-1}$
Motivation - single reference Coupled Cluster (CC)

We try to replace \( H : \mathcal{H} \to \mathcal{H} \) by a model operator \( \overline{H}_0 : \mathcal{V} \to \mathcal{V} \) where \( \mathcal{V} \subset \mathcal{H} \) is a suitable subspace of \( \mathcal{H} \). We are searching a transformation \( \varphi : \mathcal{H} \to \mathcal{H} \) and consider

\[
\overline{H}_0 := P_0 \overline{H} P_0 =: P_0 \varphi^{-1} \circ H \circ \varphi P_0 : \mathcal{V} \to \mathcal{V}
\]

where \( P_0 : \mathcal{H} \to \mathcal{V} \). For example the CC ansatz

\[
\Psi = e^T \Phi \in \mathcal{H} \text{ where } \Phi \in \mathcal{V}
\]

\[
\overline{H} := \varphi^{-1} \circ H \circ \varphi = e^{-T} H e^T, \quad \mathcal{H} \to \mathcal{H}
\]

Notice that \( \overline{H} \) is NOT Hermitean (or symmetric)!

Example: \( \mathcal{V} := \text{span}\{\phi_0\} \) where \( \phi_0 \) is a single Slater determinant

e.g HF determinant: standard CC

\[
\overline{H}_0 \phi_0 = E_{\text{CC}} \phi_0
\]
State Universal CC with CASCC

Manifold of *oblique* $n$-dimensional projectors:

$$
\mathcal{P}_n := \left\{ P = P^2 \mid \text{Trace}P = n \right\} \subset \mathcal{L}(\mathcal{H} \rightarrow \mathcal{H}) ,
$$

if and only if there are *biorthogonal* sets $\tilde{B} = \{ \tilde{\psi}_i \}_{i=1}^n \subset \mathcal{H}$ and $B = \{ \psi_i \}_{i=1}^n \subset \mathcal{H}$ such that

$$
u \mapsto Pu = \sum_{i=1}^n \psi_i \langle \tilde{\psi}_i, u \rangle , \quad P = \sum_{i=1}^n |\psi_i\rangle \langle \tilde{\psi}_i| , \quad \langle \tilde{\psi}_i, \psi_j \rangle = \delta_{i,j}
$$

- For any pair of $n$-dimensional non-orthogonal subspaces $\mathcal{V} \subset \mathcal{H}$ and $\tilde{\mathcal{V}} \subset \mathcal{H}$, there is a unique projector $P$ with these spaces as left/right ranges.
- $P$ - density matrix
State Universal CC Bivariational principle

Consider the functional $S : \mathcal{P}_n \to \mathbb{C}$ given by

$$S(P) = \text{Tr}(HP) = \sum_{i=1}^{n} \langle \tilde{\psi}_i, H\psi_i \rangle$$

Problem: find $P_* \in \mathcal{P}_n$ such that $S'(P_*) = 0$ are stationary, is equivalent to the \textit{two-sided Bloch equation}

$$ (I - P_*)HP_* = 0, \quad P_*H(I - P_*) = 0 $$

Equivalently, $\mathcal{V} = P_*\mathcal{H}$ is a \textit{right invariant subspace} and $\tilde{\mathcal{V}} = P_*^\dagger\mathcal{H}$ is a \textit{left invariant subspace}, simultaneously.

The projected \textit{effective Hamiltonian} $H_{\text{eff}} = P_*HP_*$ has $n$ exact eigenvalues $E_i$ of $H$, and that $S(P_*) = \sum_{i=1}^{n} E_i$.

- In the literature, only the right Bloch equation is usually considered when developing SU-MRCC theories. This is a major component of the novelty here.
- The bivariational principle given here is a search for invariant spaces – not individual eigenvectors.
IIa

Single Reference Coupled Cluster - revisited

IIb

State Specific MR Coupled Cluster

Second quantization - revisited

Second quantization: annihilation operators:

\[ a_j \Psi[j, 1, \ldots, N] := \Psi[1, \ldots, N] \]

and := 0 if \( j \) not apparent in \( \Psi[\ldots] \).

The adjoint of \( a_b \) is a creation operator \( \nu \)

\[ a_b^\dagger \Psi[1, \ldots, N] = \Psi[b, 1, \ldots, N] = (-1)^N \psi[1, \ldots, N, b] \]

Theorem (Slater-Condon Rules)

\[ H : \mathcal{H} \rightarrow \mathcal{H} \text{ resp. } H : \mathcal{H}_{\text{FCI}} \rightarrow \mathcal{H}_{\text{FCI}} \text{ reads as (basis dependent)} \]

\[ H = F + U = \sum_{p,q} f^p_r a^\dagger_p a_r + \sum_{p,q,r,s} u^p_{rs} a^\dagger_q a^\dagger_p a_r a_s \]
Excitation operators

Single excitation operator, Let $\Psi_0 = \Psi[1, \ldots, N]$ be a reference determinant then e.g.

$$X_k^1 \Psi_0 := a_k^\dagger a_1 \Psi_0$$

$$(-1)^{-p} \Psi_1^k = \Psi[k, 2, \ldots, N] = X_k^1 \Psi_0 = X_j^k \Psi[1, \ldots, \ldots, N] = a_k^\dagger a_1 \Psi_0$$

higher excitation operators

$$X_\mu := X_{b_1, \ldots, b_k} = \prod_{i=1}^{k} X_{l_i}^{b_i} , \ 1 \leq l_i < l_{i+1} \leq N \ , \ N < b_i < b_{i+1}$$

A CI solution $\Psi = c_0 \Psi_0 + \sum_{\mu \in J} c_\mu \Psi_\mu$ can be written by

$$\Psi = \left( c_0 + \sum_{\mu \in J} c_\mu X_\mu \right) \Psi_0 , \ c_0, c_\mu \in \mathbb{R}$$

Intermediate normalization: $c_0 := 1$ i.e. $\langle \Psi, \Psi_0 \rangle = 1$ and $[X_\mu, X_\nu] = 0$
(Multi-Reference) Coupled-Cluster Ansatz

- One-particle basis, complete active space (CAS)

\[
B_{\text{cas}} = \{\psi_1, \ldots, \psi_N, \psi_{N+1}, \ldots, \psi_d\},
\]

occupied \hspace{1cm} CAS-unoccupied

\[
B_K = \{\psi_1, \ldots, \psi_N, \psi_{N+1}, \ldots, \psi_d, \psi_{d+1}, \ldots, \psi_K\},
\]

CAS \hspace{1cm} external

- Replacement of occupied by unoccupied orbitals in reference \(\Psi_0\),

\[
\Psi[1, \ldots, i_1, \ldots, i_k, \ldots, N] \quad \rightarrow \quad \Psi_\alpha = \Psi[1, \ldots, i_1', \ldots, i_k', \ldots, a_1, \ldots, a_k],
\]

gives

\[
\mathbb{B}_K = \{\Psi_0\} \cup \{\Psi_\alpha \mid \alpha \in I_K\}.
\]

Indices: \(i, j := 1, \ldots, N\) - occupied ; \(a, b := N + 1, \ldots, d\) - (unocc.) CAS ; \(u, v = d + 1, \ldots, K\) - external,
\(z = K + 1 \ldots, \infty\) virtual
Coupled-Cluster Ansatz

- Intermediate normalization \( \langle \Psi, \Psi_0 \rangle := 1 \), \( \langle \Psi_0, \Psi_0 \rangle := 1 \)

- Galerkin Full CI (CAS) solution \( \Psi \) is expressed by excitations,

\[
\Psi = \Psi_0 + \Psi^* = \Psi_0 + \sum_{\mu \in J} s_\mu \Psi_\mu
\]

- Coupled-Cluster-Ansatz:

Nonlinear Parametrisation for \( \Psi = \Psi_0 + \Psi^* \):

cluster operator \( T =: T(t) = \sum_{\mu \in J} t_\mu X_\mu \) such that

\[
\Psi = e^{T(t)} \Psi_0,
\]

\[
\langle X_\mu \Psi_0, He^{T(t)} \Psi_0 \rangle = E \langle X_\mu \Psi_0, e^{T(t)} \Psi_0 \rangle \quad \forall \, \mu \in J \cup \{0\}.
\]

Remark. The BCH expansion terminates and is computable!
Coupled-Cluster Ansatz

- Intermediate normalization $\langle \psi, \psi_0 \rangle := 1, \langle \psi_0, \psi_0 \rangle := 1$!!
- Galerkin Full CI (CAS) solution $\psi$ is expressed by excitations,

$$
\psi = \psi_0 + \psi^* = \psi_0 + \sum_{\mu \in J} s_\mu X_\mu \psi_0 =: (I + S(s))\psi_0
$$

- Coupled-Cluster-Ansatz:

Nonlinear Parametrisation for $\psi = \psi_0 + \psi^*$:

cluster operator $T =: T(t) = \sum_{\mu \in J} t_\mu X_\mu$ such that

$$
\psi = e^{T(t)}\psi_0,
$$

$$
\langle X_\mu \psi_0, e^{-T(t)} He^{T(t)} \psi_0 \rangle = E \langle \psi_\mu, \psi_0 \rangle = E \delta_{0,\mu} \forall \mu
$$

Remark. The BCH expansion terminates and is computable!
Coupled Cluster Method - Exponential-ansatz

Theorem (S. 06)

Let \( \Phi_0 \) be a reference Slater determinant, e.g. \( \Phi_0 = \Psi_{HF} \) and \( \Psi \in \mathcal{H}_{FCI} \), satisfying

\[
\langle \Psi, \Phi_0 \rangle = 1 \quad \text{intermediate normalization}.
\]

Then there exists an excitation operator

\( T_1 \) - single-, \( T_2 \) - double- , \ldots excitation operators)

\[
T = \sum_{i=1}^{N} T_i = \sum_{\mu \in \mathcal{J}} t_{\mu} X_{\mu} \quad \text{such that}
\]

\[
\Psi = e^T \Phi_0 = \Pi_{\mu} (I + t_{\mu} X_{\mu}) \Phi_0.
\]

Key observations: for analytic functions :

\[
f(T) = \sum_{k=0}^{N} a_k T^k \quad \text{since} \quad [X_{\mu}, X_{\nu}] = 0, \quad X_{\mu}^2 = 0, \quad T^N = 0.
\]
Ilb

State Specific MR Coupled Cluster

State Specific Multi-Reference Coupled Cluster Method

(Adamovicz, Piecuch et al. (2000) - A MR CC keeping all elegance of SR CC
Ansatz: Given FCI solution $\Psi_{\text{cas}} (\approx \Psi_{\text{DMRG}}$ for example)

$$\Psi = \Psi_K = e^{T^{\text{ext}} + T^{\text{cas}}} \Phi_0 := e^{T^{\text{ext}}} \Psi_{\text{cas}} ,$$

with allowed (external) excitations $T^{\text{ext}}$ (only single /doubles)

$$X^\alpha_i = a^\dagger_\alpha a_i , \; \alpha = N+1, \ldots K \; (\text{unoccupied}) \; , \; i = 1, \ldots , N \; (\text{occupied})$$

$$T^{\text{ext}} := T_1^{\text{ext}} + T_2^{\text{ext}}$$

$$T_1^{\text{ext}} = \sum t^v_i X^v_i , \; v = d + 1, \ldots , K \; \text{external}, \; T_2^{\text{ext}} \; \text{contains only} \; \mu \notin \mathcal{I}_{\text{cas}}, \; \text{which are of form}$$

$$X_\mu = X^u_{i,j} , X^a_{i,j} = X^u_i X^v_j , X^a_{i,j} = X^a_i X^v_j$$

, i.e. $\Psi_\mu = X^a_{i,j} \Psi_0 \perp \mathcal{H}_{\text{cas}}$

$$\Psi := e^{T_1^{\text{ext}} + T_2^{\text{ext}}} e^{(T_1^{\text{cas}} + T_2^{\text{cas}} + T_3^{\text{cas}} + T_4^{\text{cas}} + \ldots)} \Psi_0 := e^{T_1^{\text{ext}} + T_2^{\text{ext}}} \Psi_{\text{cas}}$$
State Specific (CAS) Coupled Cluster Method

We introduce the non symmetric CAS Hamiltonian \( \overline{H}^{\text{cas}} = \overline{H}^{\text{cas}}(t) \) on the CAS space

\[
\overline{H}^{\text{cas}}(t) = P \mathcal{H}_{\text{cas}} e^{-t^\text{ext}(t)} H e^{t^\text{ext}(t)} P \mathcal{H}_{\text{cas}}
\]

We us consider the linked (external) CC equations

\[
0 = f_\mu(t) := \langle X_\mu \phi_0, e^{-t^\text{ext}(t)} H e^{t^\text{ext}(t)} \Phi_{\text{cas}} \rangle, \quad \forall \mu \in \mathcal{I}_{\text{ext}}
\]

together with

\[
\overline{H}^{\text{cas}}(t) \Phi_{\text{cas}} = E \Phi_{\text{cas}}
\]

Then the total (CC) energy \( E \approx E_{cc} \) is an eigenvalue of \( \overline{H}^{\text{cas}} \) with right eigenvector \( \Phi_{\text{cas}} \) i.e.

\[
\overline{H}^{\text{cas}} \Phi_{\text{cas}} = E \Phi_{\text{cas}}
\]

\( \overline{H}^{\text{cas}} \) is considered as our model operator acting on \( \mathcal{H}_{\text{cas}} \)
State Universal CC

We consider $n$ first $m$ (approximate) eigenstates (e.g., the (ground) state is degenerate), (with a positive spectral gap to the next)

$$H\psi_i = E\psi_i, \ i = 1, \ldots, n, \ E = E_0, \ \langle \psi_i, \psi_j \rangle = \delta_{i,j}$$

Consider

$$\psi_j := e^{T_j} \Phi_j, \ T_j = \sum_{\mu} (t_{\mu})_j X_{\mu}, \ \mu \in \mathcal{I}_{\text{ext}}, \ \Lambda_j = \sum_{\mu} \lambda_{j,\mu} X_{\mu}$$

$$\tilde{\psi}_j := e^{-T_j^\dagger} (\tilde{\Phi}_j + \Lambda_j \phi_0), \ \tilde{\Phi}_j, \Phi_j \in \mathcal{H}_{\text{cas}}$$

we impose (bi-) orthogonality

$$\langle \tilde{\psi}_i, \psi_j \rangle = \delta_{i,j}$$

$$\delta_{i,j} = \langle \tilde{\psi}_i, \psi_j \rangle = \langle \tilde{\Phi}_i, e^{T_j - T_i} \Phi_j \rangle + \langle \Lambda_i \phi_0, e^{T_j - T_i} \Phi_j \rangle$$

$$= \langle \tilde{\Phi}_i, \Phi_j \rangle + \sum \lambda_{i,\mu} \langle X_{\mu} \phi_0, e^{T_j - T_i} \Phi_j \rangle$$
IIa

Bivariational Principle

Non-Unitary Treatment of Quantum Problems
We consider the bivariational energy functional using
\[ \langle \psi_0, \Phi_{\text{cas}} \rangle := 1 \]

\textbf{ maximize }
\[ E(\tilde{\Phi}, \Phi, t) := \frac{\langle \tilde{\Phi}, \overline{H}^{\text{cas}}(t)\Phi \rangle}{\langle \tilde{\Phi}, \Phi \rangle} \]

\textbf{ subordinated to the linked amplitude equation}
\[ 0 = f(\mu) := \langle X_\mu \phi_0, e^{-T(t)H}e^{T(t)}\Phi \rangle \forall \mu \in \mathcal{I}_{\text{ext}} \]

(constraint optimization)

Following S. Kvaal, let us introduce the Lagrangian
\[ \mathcal{L}(\tilde{\Phi}, \Phi, t, \lambda) := E(\tilde{\Phi}, \Phi, t) + \frac{1}{\langle \tilde{\Phi}, \Phi \rangle} \lambda^T f(t) \]

We are looking for the stationary points \((\tilde{\Phi}, \Phi, t, \lambda)^*\) of \(\mathcal{L}\), then 
\(\mathcal{L}((\tilde{\Phi}, \Phi, t, \lambda)^*)\) are (approximate) eigenvalues of the original \(H\)
CAS Coupled Cluster Method - Bivariational Formulation

Equivalently we can use the Lagrangian

$$\mathcal{L}(\tilde{\Phi}, \Phi, t, \Lambda, E) := \langle \tilde{\Phi}, \overline{H}^{\text{cas}}(t)\Phi \rangle + \lambda^T f(t) + E(1 - \langle \tilde{\Phi}, \Phi \rangle)$$

Working equations for $E, \Phi_{\text{cas}} \in \mathcal{H}_{\text{cas}}$ and external amplitudes $t$ are given by differentiation of $\mathcal{L}$ w.r.t. $\tilde{\Phi}, \lambda, \Phi$ and $t$:

$$\langle \delta \tilde{\Phi}, (\overline{H}^{\text{cas}}(t) - E)\Phi_{\text{cas}} \rangle = 0 \quad \forall \delta \tilde{\Phi} \in \mathcal{H}_{\text{cas}}$$

$$\langle X_\mu \phi_0, e^{-T^{\text{ext}}(t)H}e^{T^{\text{ext}}(t)}\Phi_{\text{cas}} \rangle = 0 \quad \forall \mu \in \mathcal{I}_{\text{ext}}$$

$$\langle \delta \Phi, (\overline{H}^{\text{cas}}(t) - E)^\dagger \tilde{\Phi}_{\text{cas}} \rangle = \langle \delta \Phi, \sum_\mu \lambda_\mu X_\mu \phi_0 \rangle \quad \forall \delta \Phi \in \mathcal{H}_{\text{cas}}$$

$$(Df)_t \lambda = \partial_t \mathcal{L} = \partial_t E(t)$$

where $(Df)_{\nu, \mu} := \langle X_\mu \phi_0, e^{-T^{\text{ext}}}[H, X_\nu]e^{T^{\text{ext}}}\Phi_{\text{cas}} \rangle$

denotes the CC Jacobian

In Bodenstein & Kvaal they considered $\tilde{\Psi} := e^{\tau^\dagger}(\tilde{\Phi} + \sum_\mu \lambda_\mu X_\mu \tilde{\Phi})$
State Universal CC with CASCC

We consider $n$ first eigenstates (e.g. the (ground) state $E_1$ is degenerate), (with a positive spectral gap to the next)

$$H\Psi_i = E_i \Psi_i \ , \ i = 1, \ldots, n \ , \ \langle \Psi_i, \Psi_j \rangle = \delta_{i,j}$$

Consider

$$\Psi_j := e^{T_j(t)} \Phi_j \ , \ T_j = (t_\mu) \ , \ \mu \in \mathcal{I}_{\text{ext}} \ , \ \Lambda_j = \sum_\mu \lambda_{j,\mu} X_\mu$$

$$\tilde{\Psi}_j := e^{-T_j^\dagger} (\tilde{\Phi}_j + \Lambda_j \phi_0) \ , \ \tilde{\Phi}_j, \Phi_j \in \mathcal{H}_0 := \mathcal{H}_{\text{cas}}$$

we impose (bi-) orthogonality

$$\langle \tilde{\Psi}_i, \Psi_j \rangle = \delta_{i,j}$$

where $\phi_0$ e.g is the HF determinant.

$$\delta_{i,j} = \langle \tilde{\Psi}_i, \Psi_j \rangle = \langle \tilde{\Phi}_i, e^{T_j - T_i} \Phi_j \rangle + \langle \Lambda_i \phi_0, e^{T_j - T_i} \Phi_j \rangle$$

$$= \langle \tilde{\Phi}_i, \Phi_j \rangle + \sum_\mu \lambda_{i,\mu} \langle X_\mu \phi_0, e^{T_j - T_i} \Phi_j \rangle$$
State Universal Lagrangian

We modify the Lagrangian to enforce bi-orthogonality. Let us introduce the vector valued functions

$$\Phi := (\Phi_i)_{i=1,\ldots,n}, \quad \tilde{\Phi} := (\tilde{\Phi}_i)_{i=1,\ldots,n}, \quad T := (T_i)_{i=1,\ldots,n}, \quad \Lambda_i = \left( \sum_{\mu} \lambda_{i,\mu} X_\mu \right)$$

together with a new Lagrange multiplier $$\Sigma = (\Sigma_{i,j})$$

$$\mathcal{L}(\Phi, \tilde{\Phi}, T, \Lambda) := \sum_{i,j=1}^{n} \left( \langle \tilde{\Phi}_i, e^{-T_i} He^T_j \Phi_j \rangle + \langle \Lambda_i \phi_0, e^{-T_i} He^T_j \Phi_j \rangle \right)$$

$$+ \sum_{i,j=1}^{n} \Sigma_{i,j} \left( \delta_{i,j} - \langle \Lambda_i \phi_0, e^{T_j - T_i} \Phi_j \rangle - \langle \tilde{\Phi}_i, \Phi_j \rangle \right)$$

where $$e^{-T_j} He^T_j$$ is non symmetric! and depends on $$j$$
State Universal Lagrangian -Coupled equations

The stationary points of the Lagrangian (1st order conditions) are given in weak form by

\[
\frac{\partial J}{\partial \tilde{\Phi}_i} (\delta \tilde{\Phi}_i) = \sum_{j=1}^{n} \left( \langle \tilde{\Phi}_i, e^{-T_i} H e^{T_j} \Phi_j \rangle - \langle \delta \tilde{\Phi}_i, \Phi_j \rangle \right) = 0 \quad \forall \delta \tilde{\Phi} \in \mathcal{H}_{cas} , \ i = 1, \ldots, n
\]

\[
\frac{\partial J}{\partial \Lambda_i} = \sum_{j=1}^{n} \left( \langle \phi_0, e^{-T_i} H e^{T_j} \Phi_j \rangle - \sum_{i,j} \langle \phi_0, e^{T_j - T_i} \Phi_j \rangle \right) = 0 \quad \forall \ i = 1, \ldots, n
\]

\[
\frac{\partial J}{\partial \Phi_j} (\delta \Phi) = \sum_{i=1}^{n} \left( \langle \tilde{\Phi}_i, e^{-T_i} H e^{T_j} \delta \Phi \rangle + \langle \Lambda_i \phi_0, e^{-T_i} H e^{T_j} \delta \Phi \rangle \right)
\]

\[- \sum_{i,j} \sum_{i=1}^{n} \left( \langle \Lambda_i \phi_0, e^{T_j - T_i} \delta \Phi \rangle + \langle \tilde{\Phi}_i, \delta \Phi \rangle \right) \quad \forall \delta \Phi \in \mathcal{H}_{cas} \ j = 1, \ldots, n
\]

\[
\frac{\partial J}{\partial T} (T_i) = \cdots \quad \forall i = 1, \ldots, n
\]

Complicated set of $4n$ coupled equations!!! Can it be decoupled?
**State Universal Lagrangian**

Let us consider a Lagrange to be diagonal

\[ \Sigma = \text{diag} (\delta_{i,j}) \Rightarrow \Sigma = \text{diag} (E_j) \]

Then model equations becomes decoupled

We differentiate w.r.t. \( \tilde{\phi}_j \in \mathcal{H}_{\text{cas}}, \Lambda_j \) and \( T_j = T(t_j) \) and obtain

1st order conditions

we set \( \tilde{H}_j := e^{-T_j H} e^{T_j} \), \( E_j := \frac{\langle \tilde{\psi}_j, H \psi_j \rangle}{\langle \tilde{\psi}_j, \psi_j \rangle} \)

\[ \langle \delta \tilde{\phi}, (\tilde{H}_j - E_j) \phi \rangle = 0 \ \forall \delta \tilde{\phi} \in \mathcal{H}_{\text{cas}} \]

\[ f_\mu(t_j) := \langle X_\mu \phi_0, \tilde{H}_j \phi \rangle = 0 \ \forall \mu \in \mathcal{I}_{\text{ext}} \]

\[ \sum_{\mu} \lambda_\mu \langle X_\mu \phi_0, [\tilde{H}_j, X_\nu] \phi \rangle = \text{rhs}_j(\nu) \]

There is another set of equations for the dual solutions \( \tilde{\Phi}_j \)!
State Universal Lagrangian - Dual Equations

Let us consider a diagonal $\Sigma = \text{diag} \ (E_j)$
In order to compute $\tilde{\phi}_j$, we introduce $\mathcal{I} := \text{span} \ \phi_j : j = 1, \ldots, n$} and we $\mathcal{W} \perp \mathcal{I}$ s.t. $\mathcal{H}_{\text{cas}} = \mathcal{I} \oplus \mathcal{W}$ and decompose

$$\tilde{\phi}_j := \phi'_j + \chi_j \text{ where } \chi_j \in \mathcal{W}, \phi'_j \in \mathcal{I}$$

In order to compute $\chi_j \in \mathcal{W}$ we consider

$$\langle \delta \phi, (\bar{H}_j - E_j)^\dagger (\tilde{\phi}_j + \Lambda_j \phi_0) \rangle = 0 \ \forall \delta \phi \in \mathcal{W}$$
$$\langle \delta \phi, (\bar{H}_j - E_j)^\dagger \chi_j \rangle = \langle \delta \phi, E_j \Lambda_j \phi_0 - \bar{H}_j^T \phi'_j \rangle$$

the unknown $\phi'_j = \sum_\ell c_{j, \ell} \phi_\ell \in \mathcal{I}$ can be computed applying bi-orthogonality

$$\delta_{i,j} = \langle \Lambda_i \phi_0, e^{T_j - T_i} \phi_j \rangle + \langle \phi'_i, \phi_j \rangle = \langle \Lambda_i \phi_0, e^{T_j - T_i} \phi_j \rangle + \sum_\ell c_{i, \ell} \langle \phi_\ell, \phi_j \rangle$$

$$I = R + CM \Rightarrow C = (I - R)M^{-1} \text{ where } m_{i,j} = \langle \phi_i, \phi_j \rangle$$
Density Matrix

In order to check the previous results, we compute the matrix entries

\[
\langle \tilde{\psi}_k, H \psi_j \rangle = \langle \tilde{\phi}_k, e^{-T_k} H e^{T_j} \phi_j \rangle + \langle \Lambda_k \phi_0, e^{-T_k} H e^{T_j} \phi_j \rangle \\
= E_j (\langle \phi'_k, \phi_j \rangle + \langle \chi_k, \phi_j \rangle) + E_j \langle \Lambda_k \phi_0, e^{T_j-T_k} \phi_j \rangle \\
= E_j (\langle \phi'_k, \phi_j \rangle + \langle \Lambda_k \phi_0, e^{T_j-T_k} \phi_j \rangle) = E_j \delta_{k,j}
\]

Here we have used

\[
\langle \delta, \tilde{H}_j \phi_j \rangle = E_j \langle \delta, \phi_j \rangle \text{ for all } \delta \in \mathcal{H}_{\text{cas}}
\]

since

\[
\langle X_{\mu} \phi_0, e^{-T_j} H e^{T_j} \phi_j \rangle = 0 \text{ for all } \mu \in I_{\text{ext}}.
\]

This shows that

\[
P = \sum_{j=1}^{n} |\psi_j \rangle \langle \tilde{\psi}_j|
\]

is the desired projection (density matrix). Moreover it is of diagonal form.
Remarks: CC Energy.

Let us suppress the index \( j = 1, \ldots, n \). Let \( T^{\text{ext}} = T_1 + T_2 \) (CCSD), due to normalization \( \langle \phi_0, \Psi \rangle = \langle \phi_0, \Phi \rangle := 1 \).

\[
E(t) = \langle \tilde{\Phi} + \Lambda \phi_0, e^{-T} He^T \Phi \rangle = \langle \phi_0, H\Phi \rangle + E_{\text{ext}}
\]

\[
=: \quad E_{\text{cas}} + \langle \phi_0, H(I + T_1 + T_2 + \frac{1}{2}(T_1)^2 + T_1^{\text{cas}} T_1) \phi_0 \rangle
\]

if \( T_1^{\text{ext}} = T_1 := 0 \) terms in brown are 0

We frequently choose \( T_1^{\text{ext}} := 0 \).
Remarks: Projected CAS Coupled Cluster Method

Let $T(t) := T^\text{ext} = \sum_{\mu \in \mathcal{I}_{\text{ext}}} t_\mu X_\mu$, $0 \neq \mu \in \mathcal{I}_{\text{ext}} \subset \mathcal{J}$

The unlinked projected Coupled Cluster formulation

$$0 = \langle X_\mu \phi_0, (H - E(t)) e^{T(t) + T^\text{cas}} \phi_0 \rangle =: g_\mu(t), \ t = (t_\nu)_{\nu \in \mathcal{I}_{\text{ext}}}, \ \mu \in \mathcal{I}_{\text{ext}}$$

The linked projected Coupled Cluster formulation consists in

$$0 = \langle X_\mu \phi_0, e^{-T(t)} H e^{T(t)} \Phi \rangle =: f_\mu(t), \ t = (t_\nu)_{\nu \in \mathcal{I}_{\text{ext}}}, \ \mu \in \mathcal{I}_{\text{ext}}$$

In the sequel, we suppress (neglect) $T^\text{ext}_1$ terms

**Theorem**

*(S. & Faulstich & Laestadius)* If $T^\text{ext}_1 = 0$, the both methods are equivalent

$$\Psi_{\text{linked}}^{\text{CC}} = \Psi_{\text{unlinked}}^{\text{CC}}$$

This needs not to hold if $T^\text{ext}_1 \neq 0$!
Projected CAS - Coupled Cluster Method

Let us consider the linked CC equations

\[ 0 = f(t_\mu) := \langle X_\mu \phi_0, e^{-T(t)} H e^{T(t)} \Phi \rangle, \quad \forall \mu \in \mathcal{I}_{\text{ext}} \]

**Theorem**

The solution does not depend on \( T_k^{\text{cas}} \), \( S_k^{\text{cas}} \), for \( k > 3 \) (!), in particular, we obtain the equations

\[ 0 = f(t_\mu) = \langle X_\mu \phi_0, e^{-T} H e^{T} \Phi \rangle = \langle X_\mu \phi_0, (I - T_2) H (I + T_2 + \frac{1}{2}(\hat{T}_2)^2) \Phi \rangle \]

for all \( \mu \in \mathcal{I}_{\text{ext}} \).

Solving this problem is not essentially more expensive than single reference CC!

Here we have dropped the index \( j \) since the equations decouple

The problem is to solve the FCI CAS equations, for large CAS space.
CAS Eigenvalue Problem

For external excitations \( T = T_2 = \sum_{\mu \in I_{\text{ext}}} t_{\mu} X_\mu \) we obtain (we neglect \( T_1 \) in the sequel)

**Lemma**

\[
H_{\text{cas}}^{\text{cas}}(t) = P_{\mathcal{H}_{\text{cas}}} e^{-T(t)} H e^T(t) P_{\mathcal{H}_{\text{cas}}}
\]

\[
= P_{\mathcal{H}_{\text{cas}}} H P_{\mathcal{H}_{\text{cas}}} + P_{\mathcal{H}_{\text{cas}}} H T_2 P_{\mathcal{H}_{\text{cas}}} + \frac{1}{2} P_{\mathcal{H}_{\text{cas}}} H \hat{T}_2^2 P_{\mathcal{H}_{\text{cas}}}
\]

\[
= P_{\mathcal{H}_{\text{cas}}} H (I + T_2 + \frac{1}{2} \hat{T}_2^2) P_{\mathcal{H}_{\text{cas}}}
\]

\( T_2 = \tilde{T}_2 + \hat{T}_2 \) where \( \hat{T}_2 \) contains the mixed excitation terms \( u_{i,j}^a v X_i^a X_j^v \), and \( \tilde{T}_2 \) no mixed terms.
Remark:
\[ P_{\mathcal{H}_{\text{cas}}} H(I + T_2 + \frac{1}{2} \hat{T}_2^2) P_{\mathcal{H}_{\text{cas}}} \]

involves 3-particle operators!

We recommend to use an approximate FCI solver either

- QC-DMRG (tensor trains \( \simeq \) matrix product states) or
- Monte Carlo FCI (Alavi et al.)

**Simplifications: Tailored CC**
\( \Phi \approx \Phi_{\text{cas}} \)
\[ \langle \delta \tilde{\Phi}, (H - E_{\text{cas}}) \Phi_{\text{cas}} \rangle = 0 \ \forall \delta \tilde{\Phi} \in \mathcal{H}_{\text{cas}} \]
\[ \Rightarrow \Phi_{\text{cas}} \text{ and } E_{\text{cas}} \text{ do NOT depend on } t! \]
Numerical results for TCC-DMRG

In their approach the $T^3_{cas}$ amplitudes are neglected!!!

work in progress

The use of (large) spaces $H_{\text{cas}}$ improves the stability (inf-sup constant) of the amplitude equations
Conclusions

- CAS CC avoids most problems of single reference CCSD, without compromising the elegant numerical treatment of single reference formalism.
- Excited states can be treated well, great improvement compared to equation of motion (EOM).
- Tailored CC is more a perturbational approach for improving a reference solution $\Psi_{\text{cas}}$, 1st iteration.
- Analysis is only local, i.e. $T^{\text{ext}}$ small, but it shows
  - importance of quality of reference solution $\Psi_{\text{cas}}$
  - importance of stability
  - degenerate and quasi-degenerate ground state can be computed as well
- Computational cost: CCSD (+ DMRG (for FCI))
- The CAS space must be sufficiently large (DMRG or MCFCI)!
- The solution is (only) slightly biased by the choice of reference determinant $\Psi_0$, i.e. the choice of the occupied space.
Bi-variational Formulation and Expectation Values

Why we are interested in the dual solution $\tilde{\Psi}$? However: approximating expectation values of an operator $O : \mathcal{H} \rightarrow \mathcal{H}, \langle O \rangle := \langle \Psi, O\Psi \rangle$, let $\langle \tilde{\Psi}, \Psi \rangle := 1$.

$\triangleright$ $\langle \tilde{\Phi}, (e^T)^\dagger Oe^T \Phi \rangle \approx \langle \Psi, O\Psi \rangle$ is not computable!

$\triangleright$ alternative: $\langle (\tilde{\Phi} + \Lambda \phi_0), e^{-T} O e^T \Phi \rangle = \langle \tilde{\Psi}, O\Psi_{cc} \rangle \approx \langle \Psi, O\Psi \rangle$

We may estimate

$$\left| \langle \tilde{\Psi}, Oe^T \Phi \rangle - \langle \Psi, O\Psi \rangle \right| \leq c_1 \| \Psi - \tilde{\Psi} \| + c_2 \| \Psi - e^T \Phi \|$$

Note that $e^{-T^\dagger}$ is a de-excitation operator and $e^{-T^\dagger} \mathcal{H}_{cas} = \mathcal{H}_{cas}$. Thus the first term $\| \Psi - e^{-T^\dagger} \tilde{\Phi} \|$ is relatively large!!! (In the single reference case $\tilde{\Phi} = \phi_0$! ) But $\tilde{\Psi}$ is a poor approximation of $\Psi$

This shows the importance of computing $\tilde{\Psi}$!!!

to be extended in future!!! - work in progress
Appendix - Two Lagrangian

Better: Consider the CC Lagrangian

\[ \mathcal{L}(\Phi, \tilde{\Phi}, T, \Lambda) := \frac{\langle \tilde{\Phi}, L\Phi \rangle}{\langle \tilde{\Phi}, \Phi \rangle} + \frac{1}{\langle \tilde{\Phi}, \Phi \rangle} \langle \Lambda \phi_0, L\Phi \rangle \]

we differentiate w.r.t. \( \tilde{\Phi}, \Lambda \) and \( \Phi \) and \( T = T(t) \)

\[ L = L(t) := e^{-T} H e^{T}, \ E := \frac{\langle \tilde{\Phi}, L\Phi \rangle}{\langle \tilde{\Phi}, \Phi \rangle} \]

\[ \langle \delta \tilde{\Phi}, (L - E)\Phi \rangle = 0 \ \forall \delta \tilde{\Phi} \in Y_h \]

\[ f_\mu(t) = \langle X_\mu \phi_0, L\Phi \rangle = 0 \ \forall \mu \in I_{\text{ext}} \]

\[ \sum_\mu \langle \tilde{\Phi} + \Lambda_\mu \phi_0, [L, X_\nu]\Phi \rangle = 0 \ \forall \nu \in I_{\text{ext}} \]

\[ \langle (L^\dagger - E)\tilde{\Phi}, \delta \Phi \rangle = -\langle \Lambda \phi_0, L \delta \Phi \rangle \ \forall \delta \Phi \in X_h(!!!) \]

here \( \tilde{\Psi} \in \mathcal{V}_{\text{cas}} \oplus \text{span} \{ X_\mu \phi_0 : \mu \in I_{\text{ext}} \} \)
Projection Methods - Petrov Galerkin Methods

Alternative (Bodenstein & Kvaal) Consider the CC Lagrangian

\[ \mathcal{L}(\Phi, \tilde{\Phi}, T, \Lambda) := \frac{\langle \tilde{\Phi}, L\Phi \rangle}{\langle \tilde{\Phi}, \Phi \rangle} + \frac{1}{\langle \tilde{\Phi}, \Phi \rangle} \langle \Lambda \tilde{\Phi}, L\Phi \rangle \]

we differentiate w.r.t. \( \tilde{\Phi}, \Lambda \) and \( \Phi \) and \( T = T(t) \), \( \langle \tilde{\Phi}, \Phi \rangle := 1, \)

\[
L(t) = L(t) := e^{-T} He^{T}
\]

\[
\langle \delta \tilde{\Phi}, (L - E)\Phi \rangle = 0 \ \forall \delta \tilde{\Phi} \in Y_h
\]

\[
f(t) = \langle X_\mu \tilde{\Phi}, L\Phi \rangle = 0 \ \forall \mu \in \mathcal{I}_{ext}
\]

\[
\langle (L^\dagger - E)\tilde{\Phi}, \delta \Phi \rangle + \langle \Lambda \tilde{\Phi}, L\delta \Phi \rangle = 0 \ \forall \delta \Phi \in X_h(!!!)
\]

\[
\sum_\mu \langle \tilde{\Phi} + \Lambda_\mu \tilde{\Phi}, [L, X_\nu]\Phi \rangle = 0 \ \forall \nu \in \mathcal{I}_{ext}
\]

\[
\tilde{\Psi} \in V_{cas} \oplus \text{span} \ \{ X_\mu \tilde{\Phi} : \mu \in \mathcal{I}_{ext} \}
\]
