Zonal Winds

Zonal Winds on the Gas Giants

Jupiter and Saturn Surfaces

Zonal Winds

Zonal Winds on the Gas Giants

Measured Surface \overline{u}_{ϕ}

Jupiter: Tollefson et al. (2017). Saturn: García-Melendo et al. (2011), rot. period Mankovich et al. (2019).

L_Zonal Winds

Zonal Winds on the Gas Giants

Prograde/Superrotation/Eastward - Retrograde/Subrotation/Westward

Jupiter: Tollefson et al. (2017). Saturn: García-Melendo et al. (2011), rot. period Mankovich et al. (2019).

Background

L_Zonal Winds

Zonal Winds on the Gas Giants - Comparison

 $\overline{Ro}_{\phi} = \overline{u}_{\phi}/(\Omega r_o)$

Jupiter: Tollefson et al. (2017). Saturn: García-Melendo et al. (2011), rot. period Mankovich et al. (2019).

-Zonal Winds

Zonal Winds on the Gas Giants - Comparison

Strong, broad equatorial prograde jet.

- Jupiter: ~ 120 m/s, spans $\pm 15^{\circ}$ longitude.
- Saturn: \sim 300 m/s, spans ±30° longitude.
- Flanking retrograde jets.
- Multiple jets at higher latitudes.
 - Jupiter: \sim 30 m/s, narrower.
 - Saturn: ~ 100 m/s, wider.

Background

-Zonal Winds

Zonal Winds on the Gas Giants - Depth

Measurement: Gravity Moments

- Measured in-situ for Jupiter (by Juno) and Saturn (by Cassini).
- Deep zonal winds have significant mass flux associated with them.

Assumptions

Rotation dominates. Taylor-Proudman: zonal flow is geostrophic; z-invariant. Zonal flow decay is radi

dependent.

Background

Variation with stable layer depth

Jupiter-like case at **mid-latitude** as function of the depth of the stable layer boundary for a wind velocity of **25 m/s**, characteristic latitudinal wavelength of the zonal jets inside the tangent cylinder **10,000 km**, stability $N/\Omega = 1$.

a) Decay range $d_{0.1}$,

- b) driving power,
- c) maximum value of the local

magnetic Reynolds number.

Jovian Models - Christensen & Wulff (2024)

Variation with stable layer depth

a)

Jet velocity drops tenfold over a depth of 100-300 km.

At lower MAC (shallower stable layer boundary) winds penetrate deeper into the stable layer.

- Jovian Models - Christensen & Wulff (2024)

– Results

Variation with stable layer depth

b)

The thin full line is the observed internal heat flow and the broken line is the upper bound for the total dissipative heating according to Wicht+ (2019). It is unlikely that the dissipation linked to the zonal winds substantially exceeds the internal heat flow. This would be the case if the stable layer boundary was deeper than 2,500 km

- Jovian Models - Christensen & Wulff (2024)

- Results

Variation with stable layer depth

c)

A large magnetic reynolds number would perturb the poloidal magnetic field. Such distortions are not observed. Taking $Rm_{loc} = 3$ as an upper limit requires the stable layer boundary to be no deeper than 2,600 km \rightarrow almost identical to the constraint based on the driving power.

Jovian Models - Christensen & Wulff (2024)

Variation with latitude

Insignificant variation of $d_{0.1}$ with colatitude.

Variation of power was found to be mainly due to change in angle between gravity and magnetic field.

Jovian Models - Christensen & Wulff (2024)

Jovian Models - Christensen & Wulff (2024)

Summary

- A Stably stratified Layer (SSL) does not prevent strong zonal winds from forming in overlying convective envelope.
- SSL's lead to the decay of zonal flows penetrating down from a convective region, controlled by the MAC number.
- A thermal wind balance governs the attenuation of zonal flows in the SSL.

Jovian Models - Christensen & Wulff (2024)

Summary - Shallow Stable Layer

Jovian Models - Christensen & Wulff (2024)

Summary - Shallow Stable Layer

Jovian Models - Christensen & Wulff (2024)

Summary - Shallow Stable Layer

Conclusion

For mid-high latitude jets to form on Jupiter and Saturn a Stably Stratified Layer must be located where jet quenching begins, above highly electrically conducting depths.
